You need to complete cross-modal object-entity relation extraction. The input contains two images. The second image is a local detail of the first image, which shows an object within the first image. Given a text: '**Nobel Economics Prize Goes to Pioneers in Reducing Poverty**', you need to identify the relation type between the object depicted by the second image and the entity '**Nobel Economics Prize**' in the given text. Possible relation types are: *[Possible Relation Type List]*. Possible entity Possible entity types for the object of the second image and the entity in text are: 'per (person), org (organization), loc (location), misc (miscellaneous)'. Output the thinking process in <think> </think> and the final answer (relation type) in <answer> </answer> tags.

You need to follow these intermediate thinking steps in <think> </think> to arrive at the correct answer:
<think> Step 1: Understand the content of the two given images and explain the role of the second image in the context of the first image. If the second image is very blurry or difficult to recognize, or if it only represents a minor local detail of the first image, then the final output is likely to be type 'none'.
Step 2: Determine whether the first image is relevant to the given text, and provide justification. If you find them unrelated, then the final output is likely to be type 'none'.
Step 3: If the image and text is relevant, establish a correspondence between them. Determine whether there exists an entity in the text that corresponds to the given object of the second image. If such entity exists, you can determine the final output by evaluating the relation between this entity and 'Nobel Economics Prize'.
Step 4: Based on the context in image and text, justify the entity types of the object of the second image and 'Nobel Economics Prize' in text. The entity types can only be one of the following four: per (person), org (organization), loc (location), misc (miscellaneous). If the object of the second image is difficult to recognize, then its entity type is 'misc'.
Step 5: Based on the entity types determined in the previous step, further filter the possible relation types from the candidate set. For example, if the image object is 'per' and the text entity is 'org', then the possible relation types are only those under '/per/org': /per/org/opposed_to, /per/org/leader_of, /per/org/member_of, and none. By contrast, if the types of object and entity are 'org' and 'per', as there are no relations under '/org/per' in the given candidate relations, then the only possible type is 'none'. The possible relation types for all entity type combinations should include 'none'.
Step 6: In the range of the possible types filtered by the previous step, analyze the content of the given image and text to determine the relation type between the object of the second image and text entity 'Nobel Economics Prize'. </think>
Finally, directly output the predicted relation type in <answer> </answer>, such as: '<answer>org/loc/locate_at</answer>'

Now given the gold answer that the image object type is 'per' and the text entity 'Nobel Economics Prize' type is 'misc', and the relation type between them is '/per/misc/awarded', please follow the thinking steps outlined above to output the thinking process. It should be logically coherent to ultimately derive the gold answer. Pretend you do not know the gold answer when output the intermediate steps and do not include any phrases related to 'gold answer' in the output, such as 'given the gold answer', 'derived from the gold answer', etc. If you need to output quotation marks, please use single quotes. Please generate content with this format: <think> thinking steps </think> <answer>/per/misc/awarded</answer>
